

Logiciel

# Unbound : un serveur DNS local

**Unbound** est un serveur de noms DNS, c'est à dire qu'il traduit un nom de domaine en adresse IP.<sup>1)</sup>

Il fait cette traduction :

- soit d'après sa propre config,
- soit en faisant appel à d'autres serveurs DNS.

Dans un souci d'efficacité, il peut mettre les résultats en cache.

Nous utiliserons Unbound en tant que serveur DNS sur le réseau local pour définir des domaines factices (comme on le ferait avec un fichiers hosts, mais en plus poussé et automatisé).

Le serveur **Unbound** sera installé sur un serveur du réseau local (un Raspberry Pi dans cet exemple).

## Pré-requis

- un réseau local.
- et une connexion à Internet active pour les tests.

## Installation sur la machine du serveur

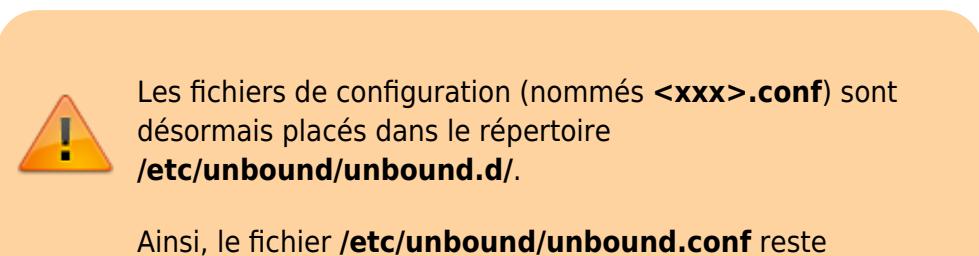

1. **Sous Linux** : installez les paquets **unbound**,**dnsutils**,**ldnsutils** ou en ligne de commande (comme sur un Raspberry Pi via SSH) :

```
...@...:~$ sudo apt install unbound dnsutils ldnsutils
```

2. **Sous Windows** : Téléchargez l'installateur **unbound\_setup\_x.x.x.exe** sur la page <http://unbound.net/download.html> et lancez-le.

## Configuration

### Sous Linux

inchangé.

Voici un exemple de fichier **local.conf** pour un serveur DNS avec déclaration automatique des sous-domaines :

</etc/unbound/unbound.conf.d/local.conf>

```
server:
    #verbosity: 1

    # Répondre aux requêtes DNS sur
    toutes les interfaces réseau.
    interface: 0.0.0.0
    port: 53

    # ouverture à tout le monde
    access-control: 0.0.0.0/0 allow
    chroot: ""

    # emplacement du fichier de log
    logfile: "/var/log/unbound.log"
    # je ne souhaite pas "pourrir"
    le syslog
    use-syslog: no

    # zone *.chateau
    local-zone: "chateau." redirect
    local-data: "chateau. IN A
    127.0.0.1"

    # zone *.framboise
    local-zone: "framboise."
    redirect
    local-data: "framboise. IN A
    127.0.0.1"

    # Utilisation du DNS "normal" (ici,
    celui de la box) pour tout le reste
    forward-zone:
        name: "."
        forward-addr: 192.168.0.254
```

Pour les options, voir la page [unbound.conf\(5\) - page de man.](#)

[Fichier exemple fourni avec unbound](#)

Voici le fichier exemple fourni avec unbound :

</usr/share/doc/unbound/examples/unbound.conf>

```
#  
# Example configuration file.  
#  
# See unbound.conf(5) man page,  
version 1.4.22.  
#  
# this is a comment.  
  
#Use this to include other text  
into the file.  
#include: "otherfile.conf"  
  
# The server clause sets the main  
parameters.  
server:  
    # whitespace is not necessary,  
but looks cleaner.  
  
        # verbosity number, 0 is least  
verbose. 1 is default.  
        verbosity: 1  
  
        # print statistics to the log  
(for every thread) every N seconds.  
        # Set to "" or 0 to disable.  
Default is disabled.  
        # statistics-interval: 0  
  
        # enable cumulative statistics,  
without clearing them after  
printing.  
        # statistics-cumulative: no  
  
        # enable extended statistics

# if given, a chroot(2) is done
to the given directory.
# i.e. you can chroot to the
working directory, for example,
# for extra security, but make
sure all files are in that
```

```
directory.  
#  
# If chroot is enabled, you  
should pass the configfile (from  
the  
# commandline) as a full path  
from the original root. After the  
# chroot has been performed the  
now defunct portion of the config  
# file path is removed to be  
able to reread the config after a  
reload.  
#  
# All other file paths (working  
dir, logfile, roothints, and  
# key files) can be specified  
in several ways:  
# o as an absolute path  
relative to the new root.  
# o as a relative path to  
the working directory.  
# o as an absolute path  
relative to the original root.  
# In the last case the path is  
adjusted to remove the unused  
portion.  
#  
# The pid file can be absolute  
and outside of the chroot, it is  
# written just prior to  
performing the chroot and dropping  
permissions.  
#  
# Additionally, unbound may  
need to access /dev/random (for  
entropy).  
# How to do this is specific to  
your OS.  
#  
# If you give "" no chroot is  
performed. The path must not end in  
a /.  
# chroot: "/etc/unbound"  
  
# if given, user privileges are  
dropped (after binding port),  
# and the given username is  
assumed. Default is user "unbound".  
# If you give "" no privileges  
are dropped.  
# username: "unbound"
```

```
        # the working directory. The  
        relative files in this config are  
            # relative to this directory.  
If you give "" the working  
directory

anchor-file probing to del anchors  
after ttl.  
      # del-holddown: 2592000 # 30  
days  
  
      # auto-trust-anchor-file  
probing removes missing anchors  
after ttl.
```

```
        # If the value 0 is given,  
        missing anchors are not removed.  
        # keep-missing: 31622400 # 366  
        days  
  
        # the amount of memory to use  
        for the key cache.  
        # plain value in bytes or you  
        can append k, m or G. default is  
        "4Mb".  
        # key-cache-size: 4m  
  
        # the number of slabs to use  
        for the key cache.  
        # the number of slabs must be a  
        power of 2.  
        # more slabs reduce lock  
        contention, but fragment memory  
        usage.  
        # key-cache-slabs: 4  
  
        # the amount of memory to use  
        for the negative cache (used for  
        DLV).  
        # plain value in bytes or you  
        can append k, m or G. default is  
        "1Mb".  
        # neg-cache-size: 1m  
  
        # By default, for a number of  
        zones a small default 'nothing  
        here'  
        # reply is built-in. Query  
        traffic is thus blocked. If you  
        # wish to serve such zone you  
        can unblock them by uncommenting  
        one  
        # of the nodefault statements  
        below.  
        # You may also have to use  
        domain-insecure: zone to make  
        DNSSEC work,  
        # unless you have your own  
        trust anchors for this zone.  
        # local-zone: "localhost."

        # a number of locally served  
        zones can be configured.  
        # local-zone: <zone> <type>  
        # local-data: "<resource  
        record string>"  
        # o deny serves local data (if  
        any), else, drops queries.  
        # o refuse serves local data  
        (if any), else, replies with error.  
        # o static serves local data,  
        else, nxdomain or nodata answer.  
        # o transparent gives local  
        data, but resolves normally for  
        other names  
        # o redirect serves the zone  
        data for any subdomain in the zone.  
        # o nodefault can be used to  
        normally resolve AS112 zones.  
        # o typetransparent resolves  
        normally for other types and other  
        names  
        #  
        # defaults are localhost  
        address, reverse for 127.0.0.1 and  
        ::1  
        # and nxdomain for AS112 zones.  
        If you configure one of these zones  
            # the default content is  
            omitted, or you can omit it with  
            'nodefault'.  
            #  
            # If you configure local-data  
            without specifying local-zone, by  
            # default a transparent local-

```
zone is created for the data.
#
# You can add locally served
data with
# local-zone: "local." static
# local-data:
"mycomputer.local. IN A 192.0.2.51"
# local-data: 'mytext.local TXT
"content of text record"'
#
# You can override certain
queries with
# local-data:
"adserver.example.com A 127.0.0.1"
#
# You can redirect a domain to
a fixed address with
# (this makes example.com,
www.example.com, etc, all go to
192.0.2.3)
# local-zone: "example.com"
redirect
# local-data: "example.com A
192.0.2.3"
#
# Shorthand to make PTR
records, "IPv4 name" or "IPv6
name".
# You can also add PTR records
using local-data directly, but then
# you need to do the reverse
notation yourself.
# local-data-ptr: "192.0.2.3
www.example.com"

# service clients over SSL (on
the TCP sockets), with plain DNS
inside
# the SSL stream. Give the
certificate to use and private key.
# default is "" (disabled).
requires restart to take effect.
# ssl-service-key:
"path/to/privatekeyfile.key"
# ssl-service-pem:
"path/to/publiccertfile.pem"
# ssl-port: 443

# request upstream over SSL
(with plain DNS inside the SSL
stream).
```

```
        # Default is no. Can be turned
        on and off with unbound-control.
        # ssl-upstream: no

        # Python config section. To enable:
        # o use --with-pythonmodule to
        configure before compiling.
        # o list python in the module-
        config string (above) to enable.
        # o and give a python-script to
        run.
        python:
            # Script file to load
            # python-script:

# Stub zones.  
# Create entries like below, to  
make all queries for 'example.com'  
and  
# 'example.org' go to the given  
list of nameservers. list zero or  
more  
# nameservers by hostname or by  
ipaddress. If you set stub-prime to  
yes,  
# the list is treated as priming  
hints (default is no).  
# With stub-first yes, it attempts  
without the stub if it fails.  
# stub-zone:  
#   name: "example.com"  
#   stub-addr: 192.0.2.68  
#   stub-prime: no  
#   stub-first: no  
# stub-zone:  
#   name: "example.org"  
#   stub-host: ns.example.com.  
  
# Forward zones  
# Create entries like below, to  
make all queries for 'example.com'  
and  
# 'example.org' go to the given  
list of servers. These servers have  
to handle  
# recursion to other nameservers.  
List zero or more nameservers by  
hostname  
# or by ipaddress. Use an entry  
with name "." to forward all  
queries.  
# If you enable forward-first, it  
attempts without the forward if it  
fails.  
# forward-zone:  
#   name: "example.com"  
#   forward-addr: 192.0.2.68  
#   forward-addr: 192.0.2.73@5355  
# forward to port 5355.  
#   forward-first: no  
# forward-zone:  
#   name: "example.org"
```

# forward-host: fwd.example.com

## Liste des serveurs DNS racines

Téléchargez le fichier **named.cache** (liste des serveurs DNS racines sur lequel s'appuiera **unbound** pour répondre aux requêtes et enregistrez-le dans le répertoire **/var/lib/unbound/** en le renommant **root.hints** :

```
$ wget ftp://FTP.INTERNIC.NET/domain/named.cache -O  
/var/lib/unbound/root.hints
```

Voici l'exemple fourni avec le paquet : [Exemple de fichier Unbound.conf](#)

### verbosity: <chiffre>

Niveau de détail des messages.

- 0 ⇒ pas de message, que les erreurs.
- **1 ⇒ informations opérationnelles.** (par défaut)
- 2 ⇒ informations opérationnelles détaillées.
- 3 ⇒ informations au niveau requête, classées par requête.
- 4 ⇒ informations au niveau de l'algorithme.
- 5 ⇒ enregistre l'identification des clients non mis en cache.

### interface: <ip address[@port]>

Interface à utiliser pour se connecter au réseau.

**Par défaut : localhost, port par défaut (fourni par le paramètre port, 53 sinon).**

Cette interface sert à l'écoute des requêtes des clients et au renvoi des réponses.

Peut être fourni plusieurs fois pour travailler sur de multiples interfaces.

Les interfaces ne sont pas modifiées par un reload (kill -HUP), mais seulement au redémarrage.

### port: <port number>

Numéro de port sur lequel le serveur répond aux requêtes.

**par défaut : 53**

### do-ip4: <yes or no>

Active ou désactive les réponses aux requêtes IP4.

**Par défaut : yes.**

do-ip6: &lt;yes or no&gt;

Active ou désactive les réponses aux requêtes IP6.

**Par défaut : yes.**

do-udp: &lt;yes or no&gt;

Active ou désactive les réponses aux requêtes UDP.

**Par défaut : yes.**

do-tcp: &lt;yes or no&gt;

Active ou désactive les réponses aux requêtes TCP.

**Par défaut : yes.**

do-daemonize: &lt;yes or no&gt;

Active ou désactive le fonctionnement en arrière-plan (comme un démon).

**Par défaut : yes.**

access-control: &lt;IP netblock&gt; &lt;action&gt;

**netblock** : plage d'adresses IP4 ou IP6 suivie de /size pour un bloc de réseau sans classes.

Actions possibles : deny, refuse, allow, allow\_snoop, deny\_non\_local ou refuse\_non\_local.

- **deny** : bloque les requêtes des hôtes de cette plage d'adresses
- **refuse** : bloque aussi les requêtes mais renvoie un message d'erreur DNS rcode REFUSED.
- **allow** autorise les requêtes des hôtes de cette plage d'adresses. N'autorise que les clients récursifs, les requêtes non récursives sont refusées.
- **allow\_snoop** autorise aussi l'accès non récursif. Cela donne un accès à la fois récursif et non récursif.
- **deny\_non\_local** : les messages non autorisés sont sautés
- **refuse\_non\_local** ils reçoivent le code d'erreur REFUSED.

Si aucun **deny** ne correspond, la correspondance de plage la plus spécifique est utilisée.

**Par défaut, seul localhost est autorisé, le reste est bloqué.**

root-hints: &lt;filename&gt;

Lire les indications de racine dans ce fichier.

**Par défaut : rien, en utilisant des builtin pour la classe IN.**

Le fichier a le format des fichiers de zone, avec seulement root names et addresses.

hide-identity: <yes or no>

hide-version: <yes or no>

Cacher les infos sur le serveur DNS.

harden-glue: <yes or no>

limite l'usurpation de DNS.

**Par défaut : yes.**

harden-dnssec-stripped: <yes or no>

Requérir les infos DNSSEC pour les zones de confiance.

**Par défaut : on.**

use-caps-for-id: <yes or no>

Ne pas tenir compte de la casse dans la requête : MonSite.com équivaut à monsite.com.

**no par défaut**

cache-min-ttl: <seconds>

valeur mini de la TTL en secondes. Ne pas dépasser 1h

**Par défaut : 0.**

prefetch: <yes or no>

activation du prefetch. Si un requête est faite lorsque la tll expire dans moins de 10% du temps qu'il lui est imparti, le cache se mettra à jour aussitôt après avoir répondu à la requête.

**Par défaut : no.**

num-threads: <number>

Le nombre de threads à créer pour servir les clients. Utilisez 1 pour pas de threading.

msg-cache-slabs: <number>

rrset-cache-slabs: <number>

infra-cache-slabs: <number>

key-cache-slabs: <number>

Nombre de slabs à utiliser . Doit être une puissance de 2 du num-threads.

rrset-cache-size: <number>

msg-cache-size: <number>

Taille du cache. A plain number is in bytes, append 'k', 'm' or 'g' for kilobytes, megabytes or gigabytes (1024\*1024 bytes in a megabyte).

**Par défaut : 4 mégaoctets.**

so-rcvbuf: <number>

Taille du buffer pour le port UPD en entrée. Évite la perte de message lors des requêtes

**Par défaut : 0** (utiliser la valeur système)

private-address: <IP address or subnet>

Give IPv4 or IPv6 addresses or classless subnets. These are addresses on your private network, and are not allowed to be returned for public

internet names. Any occurrence of such addresses are removed from DNS answers. Additionally, the DNSSEC validator may mark the answers bogus. This protects against so-called DNS Rebinding, where a user browser is turned into a network proxy, allowing remote access through the browser to other parts of your private network. Some names can be allowed to contain your private addresses, By default all the local-data that you configured is allowed to, and you can specify additional names using private-domain. No private addresses are enabled by default.

We consider to enable this for the RFC1918 private IP address space by default in later releases. That would enable private addresses for 10.0.0.0/8 172.16.0.0/12 192.168.0.0/16 169.254.0.0/16 fd00::/8 and fe80::/10, since the RFC standards say these addresses should not be visible on the public internet. Turning on 127.0.0.0/8 would hinder many spam-blocklists as they use that. Adding ::ffff:0:0/96 stops IPv4-mapped IPv6 addresses from bypassing the filter.

unwanted-reply-threshold: <number>

Si non nulles, les réponses indésirables ne sont pas seulement signalées dans les statistiques, mais aussi ajoutées à un total cumulé maintenu par thread. Quand le seuil est atteint, un avertissement est affiché et une action défensive est prise, le cache est vidé pour éviter l'empoisonnement DNS. Une valeur de 10000 est suggérée, la valeur par défaut est de 0 (service désactivé).

**Par défaut : 0 (désactivé).**

do-not-query-localhost: <yes or no>

Interdire de répondre aux requêtes du localhost ?

**Par défaut : yes** (localhost est interdit)

Si non, localhost est utilisable.

val-clean-additional: <yes or no>

Est-ce que cette section supplémentaire, doit être conservée intacte pour les données non-sécurisées ? Utile pour protéger les utilisateurs d'une validation de données potentiellement boguees. Toutes les données non signées dans la section supplémentaire seront retirées des messages sécurisés

**Par défaut : yes.**

chroot: <directory>

If chroot is enabled, you should pass the

configfile (from the commandline) as a full path from the original root. After the chroot has been performed the now defunct portion of the config file path is removed to be able to reread the config after a reload.

All other file paths (working dir, logfile, roothints, and key files) can be specified in several ways: as an absolute path relative to the new root, as a relative path to the working directory, or as an absolute path relative to the original root. In the last case the path is adjusted to remove the unused portion.

The pidfile can be either a relative path to the working directory, or an absolute path relative to the original root. It is written just prior to chroot and dropping permissions. This allows the pidfile to be /var/run/unbound.pid and the chroot to be /var/unbound, for example.

Additionally, unbound may need to access /dev/random (for entropy) from inside the chroot.

If given a chroot is done to the given directory. The default is “/usr/local/etc/unbound”.

If you give “” no chroot is performed.

username: <name>

If given, after binding the port the user privileges are dropped. Default is “unbound”. If you give username: “” no user change is performed.

If this user is not capable of binding the port, reloads (by signal HUP) will still retain the opened ports. If you change the port number in the config file, and that new port number requires privileges, then a reload will fail; a restart is needed.

directory: <directory>

Sets the working directory for the program. Default is “/usr/local/etc/unbound”. On Windows the string “%EXECUTABLE%” tries to change to the directory that unbound.exe resides in.

use-syslog: <yes or no>

Sets unbound to send log messages to the syslogd, using syslog(3). The log facility LOG\_DAEMON is used, with identity “unbound”. The logfile setting is overridden when use-syslog is turned on.

**The default is to log to syslog.**

pidfile: <filename>

The process id is written to the file.

Default is “/usr/local/etc/unbound/unbound.pid”.

So, kill -HUP `cat

/usr/local/etc/unbound/unbound.pid` triggers a reload, kill -TERM `cat /usr/local/etc/unbound/unbound.pid` gracefully terminates.

root-hints: <filename>

Read the root hints from this file.

Default is nothing, using builtin hints for the IN class. The file has the format of zone files, with root nameserver names and addresses only. The default may become outdated, when servers change, therefore it is good practice to use a root-hints file.

Voici un exemple commenté

</etc/unbound/unbound.d/mondns.com>

```
server:
  # Répondre aux requêtes DNS sur
  toutes les interfaces réseau.
  interface: 0.0.0.0
  # plage adresses ip autorisées à
  consulter le serveur dns :
  # uniquement le réseau local
  access-control: 192.168.0.0/24
  allow
  # Ignorer la casse
  # HomeServer-DIY.net sera traduit
  en homeserver-diy.net et le serveur
  et communiquera la bonne IP
  use-caps-for-id: yes
  # Renforcer la vie privée des
  adresses du LAN. Ne mettre que des
  adresses locales
  private-address: 192.168.1.0/24
```

Pour créer des DNS avec tous les sous-domaines, utiliser la directive **redirect**.

Exemple pour localhost :

```
server:
  # zone *.localhost
  local-zone: "localhost" redirect
  local-data: "localhost A 127.0.0.1"
```

Il génère tous les sous-domaines xxx.localhost, a.localhost, etc.

## Serveur DNS avec déclaration automatique des sous-domaines

Ouvrez avec les droits d'administration le fichier **/etc/unbound/unbound.conf** pour le modifier comme voulu :

Voici un exemple de fichier unbound.conf :

Nous créons ici des noms \*.dev.com

</etc/unbound/unbound.conf>

```
server:
    verbosity: 1

    interface: 192.168.0.31

    access-control: 0.0.0.0/0 allow
    chroot: ""

    logfile: "/var/log/unbound.log"
    use-syslog: no

    local-zone: "dev.com." redirect
    local-data: "dev.com. IN A 192.168.0.1"

    # Utilisation du DNS "normal" pour tout le reste (ici, celui de la
    # box)
    forward-zone:
        name: "."
        forward-addr: 192.168.0.254
```

verbosity

degré de précision des messages

interface

adresse réseau du serveur (il peut y avoir  
plusieurs lignes pour plusieurs adresses)

access-control:

0.0.0.0/0 allow

ouverture à tout le monde

logfile:

emplacement du fichier de log

use-syslog: no

pour ne pas "pourrir" le syslog

local-zone:

```

la zone *.dev.com

local-zone: "dev.com." redirect
            crée les redirections
local-data: "dev.com. IN A 192.168.0.1"
            IP de la machine qui sert ce
            domaine et ses sous-domaines

forward-zone:
            Utilisation du DNS "normal" pour tout le reste

            name: "."
            pour tout le reste
            forward-addr: 192.168.0.254
            DNS de la box

```

## Test

Lancez :

```
...@...:~ $ unbound-checkconf
```

## Exemples

Exemple fourni avec le paquet

</etc/unbound/unbound.d/monserveurdns.com>

```

root-hints: "/var/unbound/named.cache"

```

avec un utilisateur dédié créé par :

- sudo groupadd unbound
   
sudo useradd -d /var/unbound -m -g unbound -s /bin/false unbound

Le répertoire /var/unbound sera utilisé par Unbound et contiendra les fichiers de config.

## Bloquer les pubs sur internet

De nombreuses pages web contiennent du code qui affiche des pubs en s'appuyant sur les noms de domaines des régies publicitaires de google, yahoo etc. Lors du chargement de la page, votre ordinateur fera donc une requête DNS pour résoudre les domaines de ces régies.

Pour bloquer ces pubs, il suffit de configurer **unbound** pour qu'il retourne une adresse IP non attribuée du réseau local. Mais celle du localhost de l'exemple fonctionne aussi très bien. Voici ce qu'il suffit d'ajouter à la fin du fichier unbound.conf:

```
local-zone: "doubleclick.net" redirect
local-data: "doubleclick.net A 127.0.0.1"
local-zone: "googlesyndication.com" redirect
local-data: "googlesyndication.com A 127.0.0.1"
local-zone: "googleadservices.com" redirect
local-data: "googleadservices.com A 127.0.0.1"
local-zone: "google-analytics.com" redirect
local-data: "google-analytics.com A 127.0.0.1"
local-zone: "ads.youtube.com" redirect
local-data: "ads.youtube.com A 127.0.0.1"
local-zone: "adserver.yahoo.com" redirect
local-data: "adserver.yahoo.com A 127.0.0.1"
```

Cette liste n'est pas exhaustive ; le fichier suivant contient un grand nombre de domaines utilisés par un grande nombre de régies publicitaires : [Regies pub.odt](#)

## Sous Windows

La configuration se fait en éditant le fichier **C:\Program Files\Unbound\unbound.conf**.

A ce même endroit se trouve un fichier exemple **C:\Program Files\Unbound\example.conf** que l'on peut recopier en le renommant **unbound.conf** pour partir de cette base.

## Utilisation

### Sous ubuntu

#### Contrôle

##### 1. Relancer le service :

```
...@...:~ $ sudo service unbound restart
```

##### 2. Démarrer **unbound** :

```
...@...:~ $ sudo systemctl start unbound
```

### 3. Arrêter **unbound** :

```
...@...:~ $ sudo systemctl stop unbound
```

### 4. Redémarrer **unbound** :

```
...@...:~ $ sudo systemctl restart unbound
```

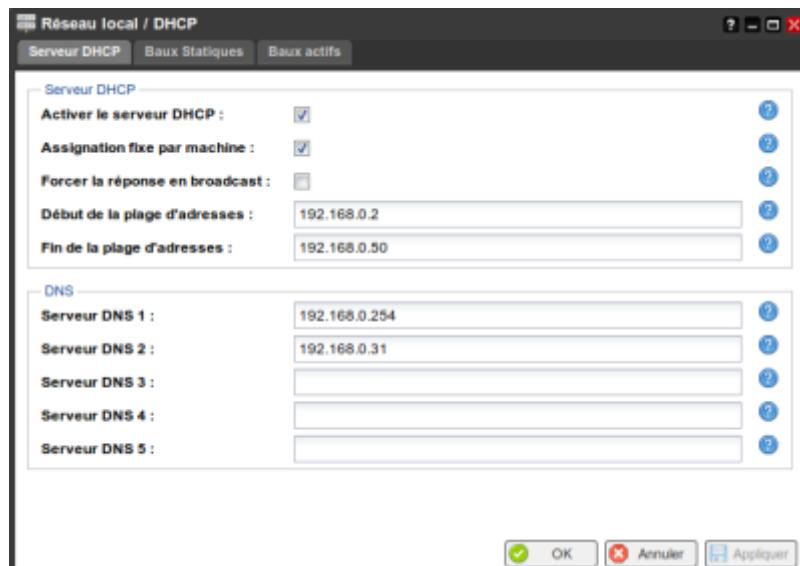

### 5. Connaître l'état d'**unbound** :

```
...@...:~ $ sudo systemctl status unbound
```

## Sous Windows

### Utilisation depuis les autres machines

Le plus simple est d'utiliser le protocole DHCP : déclarez sur votre box l'adresse de votre serveur hébergeant unbound pour que toutes vos machines utilisent ce nouveau service auto-hébergé:

## Désinstallation

- Pour supprimer cette application, il suffit de supprimer son paquet :

```
...@...:~ $ sudo apt-get remove unbound
```

- ou pour effacer tout :

```
...@...:~ $ sudo apt-get purge unbound
```

---

Basé sur « [manuel](#) » par *unbound*.

1)

C'est une alternative plus simple à configurer que **bind9** pour un LAN de petite taille.
